

Dyfi - tidal limit to Afon Twymyn

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Dyfi - tidal limit to Afon Twymyn planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Dyfi - tidal limit to Afon Twymyn catchment. The River Dyfi flows into the sea near Aberdyfi. Machynlleth and Glantwymyn are the largest urban areas.

This planning catchment consists of 12 wastewater catchments (see Figure 2). There is a combined population of 4864, this is set to decrease to 4000 by 2050, a change of -18%. There is a total sewer length of 52km, with a foul sewer length of 27km, a surface water length of 9.1km and a combined sewer length of 14km. There are 12 Wastewater Treatment Works (WwTW), 13 Sewerage Pumping Stations (SPSs), and 9 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u> Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Dyfi - tidal limit to Afon Twymyn region is set to decrease to 4000 by 2050, a change of -18% based on our future

projections. For a further a breakdown of population change in the L3 region please see the L4 report. There are major developments in localised areas that will contribute to future pressures on the network, including Machynlleth - site adjacent Tan y Bryn

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Dyfi - tidal limit to Afon Twymyn catchment the biggest risks indicated by the RBCS are - catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography).

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, sewer collapses are the biggest concern in the Dyfi - tidal limit to Afon Twymyn catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, sewer collapses are the biggest concern in the Dyfi - tidal limit to Afon Twymyn catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

Figure 6 - Associated Strategic Planning Area priority (2025)

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Moderate	Poor	Bad
Dyfi - tidal limit to Afon Twymyn	15	9	6	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Ke	ey
Dyfi - tidal limit to Afon Twymyn	Headroom							Pass	Close fail
								Close Pass	Fail
	Wet weather capacity							>90%	70%-80%
								80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Dyfi - tidal limit to Afon Twymyn catchment the balance between supply and demand currently passes the assessment criteria available, for headroom only, and will continue to pass through to 2050. It should be noted that local issues are present in the Cemaes Road L4 catchment. Further detail is provided in the relevant L4 summary.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience						
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term				
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term				
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term				
	Improving Headroom					
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term				
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term				
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term				

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Maintain existing performance*	-	£17,000,000.00	£29,000,000.00
40 spills in a typical year	£4,000,000.00	£4,000,000.00	£4,000,000.00
20 spills in a typical year	£5,000,000.00	£5,000,000.00	£5,000,000.00
10 spills in a typical year	£6,000,000.00	£6,000,000.00	£6,000,000.00
0 spills in a typical year	£18,000,000.00	£18,000,000.00	£23,000,000.00
Equivalent No. Principality Stadiums full of water in 10 spills	27.00	30.00	32.00

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£5,400,000.00	£6,500,000.00	£9,900,000.00
External escapes in gardens	£0.00	£0.00	£0.00
Escapes in highways	£2,000,000.00	£2,400,000.00	£3,700,000.00
All other remaining flooding	-	£0.00	£0.00
Total	£7,400,000.00	£8,900,000.00	£13,600,000.00

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Appendix B - Risk Based Catchment Screening

Table B1 -	Risk Based	Catchment Screenin	ng (RBCS) indicators

Indicator	Description
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme wet weather event.
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).
Discharge to sensitive waters (part A)	Mechanism to understand the significance of
Discharge to sensitive receiving (part B) (Tier 2)	environmental receptors.
SOAF	Considers current / potentially future activity instigated by SOAF procedures.
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.
M/WTM/O compliance	Historical measure relating to the performance

wwwwwwwqcompnance	compliance (numeric)).
WwTW DWF compliance	Historical measure of compliance with flow permits.
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.
Bespoke Indicators (Tier 2)	Not applied in cycle 1.

DWMP Strategic Planning Area Summary

Dysynni - lower

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Dysynni - lower planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Dysynni - lower catchment Is at the southern extent of Snowdonia National Park, Bordering the Irish Sea in the West. The River Dysynni flows down to The sea near Tywyn. Tywyn and Bryncrug are its largest urban areas.

This planning catchment consists of 4 wastewater catchments (see Figure 2). There is a combined population of 8287, this is set to decrease to 7100 by 2050, a change of -15%. There is a total sewer length of 61km, with a foul sewer length of 8km, a surface water length of 2.6km and a combined sewer length of 50km. There are 4 Wastewater Treatment Works (WwTW), 21 Sewerage Pumping Stations (SPSs), and 7 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u>

Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Dysynni - lower region is set to decrease to 7100 by 2050, a change of -15% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network, including two in Tywyn - land Pendre and Bryncrug - land near Clydfan

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Dysynni - lower catchment the biggest risks indicated by the RBCS are - catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography).

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, sewer collapses are the biggest concern in the Dysynni - lower catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, pollution due to storms and external flooding due to blockages are the biggest concern in the Dysynni - lower catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

Figure 6 - Associated Strategic Planning Area priority (2025)

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Good Moderate		Bad
Dysynni - lower	6	1	5	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Ke	еу
Dysynni - lower	Headroom							Pass	Close fail
								Close Pass	Fail
	Wet weather capacity							>90%	70%-80%
	capacity							80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Dysynni - lower catchment the balance between supply and demand currently passes the assessment criteria avaliable, for headroom only, and will continue to pass through to 2050. It should be noted that local issues are present in the Llanegryn L4 catchment. Further detail is provided in the relevant L4 summary.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience						
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term				
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term				
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term				
	Improving Headroom					
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term				
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term				
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term				

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Maintain existing performance*	-	£9,000,000.00	£12,000,000.00
40 spills in a typical year	£1,000,000.00	£1,000,000.00	£1,000,000.00
20 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00
10 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00
0 spills in a typical year	£9,000,000.00	£12,000,000.00	£13,000,000.00
Equivalent No. Principality Stadiums full of water in 10 spills	6.00	7.00	8.00

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£300,000.00	£300,000.00	£300,000.00
External escapes in gardens	£0.00	£0.00	£0.00
Escapes in highways	£2,000,000.00	£2,400,000.00	£3,700,000.00
All other remaining flooding	-	£0.00	£0.00
Total	£2,300,000.00	£2,700,000.00	£4,000,000.00

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Table A1 - Number of schemes in L4 catchment within L3 catchment

L4 Catchments	No. Schemes
LLANEGRYN STW	0
ABERGYNOLWYN	0
BRYNCRUG STW	0
TYWYN	3

Appendix B - Risk Based Catchment Screening

Table B1 -	Risk Based	Catchment Screenin	g (RBCS) indicators

Indicator	Description	
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme wet weather event.	
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).	
Discharge to sensitive waters (part A)	Mechanism to understand the significance of any impact of water company operations on environmental receptors.	
Discharge to sensitive receiving (part B) (Tier 2)		
SOAF	Considers current / potentially future activity instigated by SOAF procedures.	
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.	
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).	
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).	
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.	
M/WT/M/ O compliance	Historical measure relating to the performance	

wwwwwwwqcompliance	compliance (numeric)).
WwTW DWF compliance	Historical measure of compliance with flow permits.
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.
Bespoke Indicators (Tier 2)	Not applied in cycle 1.

DWMP Strategic Planning Area Summary

Eden - upper

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Eden - upper planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Eden - upper catchment Is south of the Llyn peninsula and slightly inland from cardigan Bay. The River Eden joins the River Mawddoch near Ganllwyd, and on to the sea at Barmouth. Bronaber is the largest urban area.

This planning catchment consists of 1 wastewater catchments (see Figure 2). There is a combined population of 403, this is set to decrease to 300 by 2050, a change of -34%. There is a total sewer length of 2km, with a foul sewer length of 1km, a surface water length of 0km and a combined sewer length of 1km. There are 1 Wastewater Treatment Works (WwTW), 0 Sewerage Pumping Stations (SPSs), and 1 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u> Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Eden - upper region is set to decrease to 300 by 2050, a change of -34% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 **Risk Based Catchment Screening**

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Eden - upper catchment the biggest risk indicated by the RBCS is - Water Industry National **Environment Programme.**

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results
3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, sewer collapses are the biggest concern in the Eden - upper catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, pollution due to storms and external flooding due to blockages are the biggest concern in the Eden - upper catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

Figure 6 - Associated Strategic Planning Area priority (2025)

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Moderate	Poor	Bad
Eden - upper	3	0	3	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Кеу	
Eden - upper	Headroom							Pass	Close fail
								Close Pass	Fail
	Wet weather capacity							>90%	70%-80%
								80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Eden - upper catchment the balance between supply and demand currently passes the assessment criteria available, for headroom only, and will continue to pass through to 2050. There are currently no local issues present in the L4 catchments.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience							
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term					
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term					
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term					
	Improving Headroom						
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term					
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term					
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term					

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Maintain existing performance*	-	£3,000,000.00	£5,000,000.00
40 spills in a typical year	£1,000,000.00	£1,000,000.00	£1,000,000.00
20 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00
10 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00
0 spills in a typical year	£4,000,000.00	£4,000,000.00	£4,000,000.00
Equivalent No. Principality Stadiums full of water in 10 spills	10.00	12.00	13.00

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£0.00	£0.00	£0.00
External escapes in gardens	£0.00	£0.00	£0.00
Escapes in highways	£0.00	£0.00	£0.00
All other remaining flooding	-	£0.00	£0.00
Total	£0.00	£0.00	£0.00

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Table A1 - Number of schemes in L4 catchment within L3 catchment

L4 Catchments	No. Schemes
BRONABER (N OF DOLGELLAU)	0

Appendix B - Risk Based Catchment Screening

Table B1 -	Risk Based	Catchment Screenin	ng (RBCS) indicators

Indicator	Description
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme wet weather event.
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).
Discharge to sensitive waters (part A)	Mechanism to understand the significance of
Discharge to sensitive receiving (part B) (Tier 2)	environmental receptors.
SOAF	Considers current / potentially future activity instigated by SOAF procedures.
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.
M/WTM/O compliance	Historical measure relating to the performance

wwwwwwwqcompnance	compliance (numeric)).
WwTW DWF compliance	Historical measure of compliance with flow permits.
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.
Bespoke Indicators (Tier 2)	Not applied in cycle 1.

DWMP Strategic Planning Area Summary

laen - lower

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The laen - lower planning catchment lies within the Meirionnydd catchment (see Figure 1).

The laen - lower catchment Is in West Wales. The River Rhiw Saeson joins the River Twymyn to flow down to the River Dyfi near Glantwymyn . Llanbrynmair and Llan are its largest urban areas.

This planning catchment consists of 3 wastewater catchments (see Figure 2). There is a combined population of 711, this is set to decrease to 600 by 2050, a change of -16%. There is a total sewer length of 8km, with a foul sewer length of 8km, a surface water length of 0km and a combined sewer length of 0km. There are 3 Wastewater Treatment Works (WwTW), 3 Sewerage Pumping Stations (SPSs), and 1 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 1 - River basin location detailing the strategic planning area Data is available from https://www.openstreetmap.org/copyright © OpenStreetMap contributors

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 **Stakeholder Engagement**

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here:

Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u> Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the laen - lower region is set to decrease to 600 by 2050, a change of -16% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network, including Llanbrynmair - land west of Bryncoch

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 **Risk Based Catchment Screening**

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the laen - lower catchment the biggest risks indicated by the RBCS are catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography) and other RMAs.

RBCS Results

Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 **Baseline Risk And Vulnerability Assessment (BRAVA)**

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, sewer collapses are the biggest concern in the laen - lower catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, sewer collapses are the biggest concern in the laen - lower catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

BRAVA results 2050 Flooding and Pollution caused by Hydraulic Overload No known risk

Figure 6 - Associated Strategic Planning Area priority (2025)

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Moderate	Poor	Bad
laen - lower	7	5	2	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Кеу	
laen - lower	Headroom							Pass	Close fail
								Close Pass	Fail
	Wet weather capacity							>90%	70%-80%
								80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the laen - lower catchment the balance between supply and demand currently passes the assessment criteria available, for headroom only, and will continue to pass through to 2050. There are currently no local issues present in the L4 catchments.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience						
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term				
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term				
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term				
	Improving Headroom					
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term				
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term				
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term				

Table 4 - Scheme types

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)		
Maintain existing performance*	-	£3,000,000.00	£5,000,000.00		
40 spills in a typical year	£1,000,000.00	£1,000,000.00	£1,000,000.00		
20 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00		
10 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00		
0 spills in a typical year	£4,000,000.00	£4,000,000.00	£4,000,000.00		
Equivalent No. Principality Stadiums full of water in 10 spills	37.00	41.00	45.00		

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)	
Internal escapes	£0.00	£0.00	£0.00	
External escapes in gardens	£0.00	£0.00	£0.00	
Escapes in highways	£0.00	£0.00	£0.00	
All other remaining flooding	-	£0.00	£0.00	
Total	£0.00	£0.00	£0.00	

 $\ensuremath{^*\textsc{Internal}}$ escapes - All flooding that results in flooding within a property is stopped

 * External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Appendix B - Risk Based Catchment Screening

Table B1 - Risk Based Catchment Screening (RBCS) indicators

Indicator	Description				
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme we weather event.				
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations o environmental receptors (bathing or shellfis waters).				
Discharge to sensitive waters (part A)	Mechanism to understand the significance of any impact of water company operations on environmental receptors.				
Discharge to sensitive receiving (part B) (Tier 2)					
SOAF	Considers current / potentially future activity instigated by SOAF procedures.				
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.				
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).				
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).				
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.				
WwTW O compliance	Historical measure relating to the performance				

wwwwwwwqcompnance	compliance (numeric)).			
WwTW DWF compliance	Historical measure of compliance with flow permits.			
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non-compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).			
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.			
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.			
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.			
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.			
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.			
Bespoke Indicators (Tier 2)	Not applied in cycle 1.			

DWMP Strategic Planning Area Summary

Leri - lower

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Leri - lower planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Leri - lower catchment is in West Wales, directly south of the Dyfi Estuary. The River Leri flows down to the Dyfi Estuary alongside the Dyfi National Nature Reserve. Borth and Talybont are its largest urban areas.

This planning catchment consists of 2 wastewater catchments (see Figure 2). There is a combined population of 3628, this is set to decrease to 2600 by 2050, a change of -29%. There is a total sewer length of 29km, with a foul sewer length of 19km, a surface water length of 0km and a combined sewer length of 9km. There are 2 Wastewater Treatment Works (WwTW), 10 Sewerage Pumping Stations (SPSs), and 2 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u>

Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Leri - lower region is set to decrease to 2600 by 2050, a change of -29% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network, including Llanbrynmair - land west of Bryncoch

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Leri - lower catchment the biggest risks indicated by the RBCS are catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography), planned residential development and other RMAs.

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, external flooding due to blockages and storms are the biggest concern in the Leri - lower catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, external flooding due to blockages and storms, pollution due to blockages and treatment works - storm flow compliance are the biggest concern in the Leri - lower catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

Figure 6 - Associated Strategic Planning Area priority (2025)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total Good		Moderate	Poor	Bad
Leri - lower	4	1	3	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Кеу	
	Headroom							Pass	Close fail
								Close Pass	Fail
Leri - lower	Wet weather capacity							>90%	70%-80%
								80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Leri - lower catchment the balance between supply and demand currently passes the assessment criteria avaliable, for headroom only, and will continue to pass through to 2050. There are currently no local issues present in the L4 catchments.
5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience				
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term		
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term		
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term		
Improving Headroom				
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term		
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term		
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term		

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Maintain existing performance*	-	£0.00	£0.00
40 spills in a typical year	£0.00	£0.00	£0.00
20 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00
10 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00
0 spills in a typical year	£5,000,000.00	£5,000,000.00	£5,000,000.00
Equivalent No. Principality Stadiums full of water in 10 spills	2.00	2.00	2.00

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£1,000,000.00	£1,200,000.00	£1,600,000.00
External escapes in gardens	£600,000.00	£700,000.00	£600,000.00
Escapes in highways	£6,000,000.00	£7,300,000.00	£11,100,000.00
All other remaining flooding	-	£0.00	£0.00
Total	£7,600,000.00	£9,200,000.00	£13,300,000.00

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Appendix B - Risk Based Catchment Screening

Table B1 -	Risk Based	Catchment Screenin	ng (RBCS) indicators

Indicator	Description		
Catchment Characterisation (Tier 2)	Provides a mechanism to understand th vulnerability of the catchment/subcatchment to sewer flooding as a result of an extrem wet weather event.		
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).		
Discharge to sensitive waters (part A)	Mechanism to understand the significance of		
Discharge to sensitive receiving (part B) (Tier 2)	environmental receptors.		
SOAF	Considers current / potentially future activity instigated by SOAF procedures.		
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.		
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).		
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).		
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.		
M/WTM/O compliance	Historical measure relating to the performance		

wwwwwwwqcompnance	compliance (numeric)).
WwTW DWF compliance	Historical measure of compliance with flow permits.
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.
Bespoke Indicators (Tier 2)	Not applied in cycle 1.

DWMP Strategic Planning Area Summary

Mawddach - Iower

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Mawddach - lower planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Mawddach - lower catchment is in West Wales, bordering the Irish sea to the West. The Rivers Mawddach and Wnion flow down to the sea at Barmouth. Dolgellau and Barmouth are its largest urban areas.

This planning catchment consists of 11 wastewater catchments (see Figure 2). There is a combined population of 12910, this is set to decrease to 7000 by 2050, a change of -45%. There is a total sewer length of 83km, with a foul sewer length of 12km, a surface water length of 6.21km and a combined sewer length of 61km. There are 11 Wastewater Treatment Works (WwTW), 34 Sewerage Pumping Stations (SPSs), and 28 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u> Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm

intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Mawddach - lower region is set to decrease to 7000 by 2050, a change of -45% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network, including Dolgellau - site adjacent to Wenallt

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Mawddach - lower catchment the biggest risks indicated by the RBCS are - catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography).

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, external flooding due to blockages and sewer collapses are the biggest concern in the Mawddach - lower catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, external flooding due to blockages and sewer collapses are the biggest concern in the Mawddach - lower catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to be in the Extended or Complex category and required a more detailed option assessment.

Figure 6 - Associated Strategic Planning Area priority (2025)

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Moderate	Poor	Bad
Mawddach - lower	12	7	4	1	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Ke	еу
	Headroom							Pass	Close fail
								Close Pass	Fail
Mawddach - Iower	Wet weather capacity							>90%	70%-80%
	. ,							80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Mawddach - lower catchment the balance between supply and demand currently passes the assessment criteria available, for headroom only, and will continue to pass through to 2050. There are currently no local issues present in the L4 catchments.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience				
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term		
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term		
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term		
Improving Headroom				
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term		
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term		
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term		

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Maintain existing performance*	-	£56,000,000.00	£79,000,000.00
40 spills in a typical year	£11,000,000.00	£12,000,000.00	£12,000,000.00
20 spills in a typical year	£21,000,000.00	£21,000,000.00	£22,000,000.00
10 spills in a typical year	£36,000,000.00	£36,000,000.00	£42,000,000.00
0 spills in a typical year	£72,000,000.00	£82,000,000.00	£84,000,000.00
Equivalent No. Principality Stadiums full of water in 10 spills	145.00	161.00	176.00

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£700,000.00	£800,000.00	£1,200,000.00
External escapes in gardens	£1,600,000.00	£2,400,000.00	£1,600,000.00
Escapes in highways	£12,800,000.00	£16,000,000.00	£21,800,000.00
All other remaining flooding	-	£0.00	£0.00
Total	£15,100,000.00	£19,200,000.00	£24,600,000.00

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

River Basin Catchment Summary

Meirionnydd

How to read this document

This document outlines detail relating to the planning areas of our DWMP.

The document has been structured to begin by outlining the information for Strategic Planning Units (Level 2) and then proceeds onto detailing the Tactical Planning Units (Level 3).

The reader is advised to scroll down the document until they find the appropriate section.

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment.

1.1 Catchment Information

Meirionnydd (see Figure 1) consists of 41 wastewater catchments with a total population of 131178. There is a total sewer length of 300km, where 80km is associated to the foul system, 20km is associated to the surface water system and 186km is associated to the combined system. There are 41 Wastewater Treatment Works (WwTW), 190 Sewerage Pumping Stations (SPSs), and 191 Combined Storm Overflows (CSOs) across this river basin catchment level.

The Meirionnydd catchment covers parts of the counties of Gwynedd, Ceredigion and Powys. The River Dyfi and the River Mawddach are the main rivers in the catchment.

Figure 1 - River basin location detailing associated strategic planning areas Data is available from https://www.openstreetmap.org/copyright © OpenStreetMap contributors

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans. Table 1 details the main opportunities we have identified but this is not intended to be exhaustive. Note that these stakeholders have their own planning processes and plans which do not necessarily align with those of DCWW.

In collaboration with our stakeholders, we have produced the following documents at the completion of each stage of the DWMP:

• Strategic Context: 'Introduction to the Drainage and Wastewater Management Plan', a Strategic Context document with details of the six national planning objectives and the DWMP action plan. A customer overview of the 'Introduction to the Drainage and Wastewater Management Plan', document which summarises what is included in the DWMP and why and how we created it has also been published.

• Risk Assessment: 'Where we want to work with you', which details our vision for future joint working on current and future risks.

• Options Development: An Options Development document is currently being developed with stakeholders and will be published later in 2023. This document will communicate how we have developed options that apply across all areas.

• Programme Appraisal: We are developing a 'Programme Appraisal' document in conjunction with our Options Development Option which will be published in 2023 and will outline how we take preferred solutions from the Options Development Process and develop a programme of work and timescales to implement them.

• Consultation: We produced this DWMP Plan, along with supporting documents to help stakeholders and customers make informed decisions at the consultation stage. Supporting documents to the DWMP include: a Customer Version DWMP; a DWMP brochure and questionnaire and a non-technical document. These were all published for the public consultation between July and October 2022.

• Following on from the consultation, we have produced a Statement of Response and a customer version Statement of Response to provide our stakeholders and customers with our responses to the items raised as part of the consultation.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

WALES FLOOD AND COASTAL CAPITAL INVESTMENT 2022-23

Figure 2 - Flood and Coastal Investment overview

Data is available from: https://gov.wales/flood-and-coastal-erosion-risk-management-programme-2022-2023

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much the population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how surface water connected to the sewer network may increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u>

Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall is predicted to happen more frequently.

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

The population in the Meirionnydd region is set to decrease to 108100 by 2050, a change of -18% based on our future projections. However there are major developments in localised areas that will contribute to future pressures on the network, including Tywyn - Tir Pendre and Borth - near Craig yr Wylfa school. For a further breakdown of population change in the L2 region, please see the L3 reports.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments are passed through to a more detailed risk assessment (BRAVA).

For the Meirionnydd region the biggest risks indicated by the RBCS are region characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography), other RMA systems (risk of interaction between other drainage systems) and external sewer flooding.

RBCS Results

* To sewer flooding due to extreme wet weather events.
To sever flooding due to extreme wet weather events.

** Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

*** Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+ Frequency investigation triggered.

++Overflow risks not covered by other indicators.

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment in Meirionnydd.

BRAVA Results - 2025

Figure 4 - BRAVA 2025 Summary

BRAVA Results - 2050

Figure 5 - BRAVA 2050 Summary

In both 2025 and 2050 risk of flooding in an extreme storm is the biggest risk in the Meirionnydd region, followed by external flooding caused by blockages.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

No known risk
Pollution
Flooding
Both

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L2 Area	Total	Good	Moderate	Poor	Bad
Meirionnydd	55	25	29	1	0

Table 2 - WFD status'

4.0 Supply Demand

The supply-demand balance is an assessment of overall capacity of the network versus the current consented capacity of the treatment works. The current discharge consent includes the quality parameters which are fundamental to the current discharge consent. The presentation of the supply demand balance is showing the status of catchment in terms of the dry weather components of a network when added together compared to the current discharge consent today and into the future. In areas where this assessment shows a risk that the capacity of the network is greater than the capacity of the current discharge permit then an assessment into the route cause is required. The resultant solution could be a need to alter the discharge permit; upgrade of the treatment work; or an upgrade of stretches to the network.

Table 3 shows the supply-demand assessment for this catchment. Where a region may not have adequate capacity, it is flagged dark blue for further investigation. There may be local incapacity issues at individual treatment works within the catchment.

Table 3 - Supply Demand Balance

Table 3 shows that for the Meirionnydd region the balance between supply and demand is currently acceptable across the region and is projected to remain so through to 2050. However, it should be noted that local issues are present in the following L3 regions: Dulas North, Dyfi - tidal limit to Afon Twymyn and Dysynni - lower. For further detail please refer to the relevant L3 summary.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Figure 8 shows our Journey Plan. This describes the scheme types that are most likely to be beneficial in this region and the timescales over which solutions types might be implemented which can reduce risks to customers and the environment. We can reduce rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Journey Plan
The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding.

Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 4 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

At the time of publishing, over 200 assessments of the environmental impact of our storm overflows have been completed and by the end of 2025 this should rise to over 750 assessments. These assessments are made at individual assets across the company area. Our approach follows the Storm Overflow Assessment Framework Stage 2 assessments and includes assessment of aesthetic and visual impacts alongside water quality impact (through a combination of invertebrate or water quality modelling). We will provide an update to the area summaries when the output data becomes available.

Table 5 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 4 are in addition to those in Table 5, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)	
Maintain existing performance*	-	£104,000,000.00	£148,000,000.00	
40 spills in a typical year	£23,000,000.00	£24,000,000.00	£23,000,000.00	
20 spills in a typical year	£37,000,000.00	£36,000,000.00	£37,000,000.00	
10 spills in a typical year	£56,000,000.00	£56,000,000.00	£62,000,000.00	
0 spills in a typical year	£122,000,000.00	£141,000,000.00	£148,000,000.00	
Equivalent No. Principality Stadiums full of water in 10 spills	0.48	0.53	0.57	

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 4 - Summary of Combined Storm Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£7,000,000.00	£9,000,000.00	£13,000,000.00
External escapes in gardens	£3,000,000.00	£4,000,000.00	£3,000,000.00
Escapes in highways	£27,000,000.00	£33,000,000.00	£45,000,000.00
All other remaining flooding	-	£71,000,000.00	£47,000,000.00
Total	£37,000,000.00	£117,000,000.00	£108,000,000.00

 $\ensuremath{^*}\xspace$ Internal escapes - All flooding that results in flooding within a property is stopped

 * External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 5 - Summary of Flooding Option Investments Strategy Costs

Costs in Table 4 and 5 are strategic indications needed to bring our entire network up to the level of protection required to be resilient for future risk and demands. The range of scenarios provides a choice for understanding and discussion of future direction.

We are beginning to break down the investment indicated in Table 4 and 5 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. They have been analysed in terms of their long term benefit, environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against pollution and flooding events. Appendix A shows the number of solutions within this river basin catchment.

A summary of the options considered within suitability tests can be found in the Main Plan alongside the methodology. More detailed information can be seen in the Level 3 reports.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with the Welsh Government and our regulators.

Appendix A - Schemes in L3 catchment within L2 region

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Table A1 - Number of schemes in L3 catchment within L2 region

L3 Zones	No. Schemes

Appendix B - Risk Based Catchment Screening

Table B1 - Risk Based Catchment Screening (RBCS) indicators

Indicator	Description
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme wet weather event.
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).
Discharge to sensitive waters (part A)	Mechanism to understand the significance of any impact of water company operations on environmental receptors.
Discharge to sensitive receiving (part B) (Tier 2)	Mechanism to understand the significance of any impact of water company operations on environmental receptors.
SOAF	Considers current / potentially future activity instigated by SOAF procedures.
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.
WwTW Q compliance	Historical measure relating to the performance of the treatment works (discharge permit compliance (numeric)).

WwTW DWF compliance	Historical measure of compliance with flow permits.
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.
Bespoke Indicators (Tier 2)	Not applied in cycle 1.

DWMP Strategic Planning Area Summary

Artro

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Artro planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Artro catchment borders the coastline in the Cardigan Bay. The River Arto flows down into the sea at Llanbedr. Dyffryn Ardudwy and Llanbedr are it's major urban areas.

This planning catchment consists of 2 wastewater catchments (see Figure 2). There is a combined population of 5996, this is set to increase to 6400 by 2050, a change of 7%. There is a total sewer length of 53km, with a foul sewer length of 3km, a surface water length of 1.4km and a combined sewer length of 44km. There are 2 Wastewater Treatment Works (WwTW), 15 Sewerage Pumping Stations (SPSs), and 10 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be found <u>here, Impact of Urban Creep on Sewerage Systems.</u>

Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a 2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Artro region is set to increase to 6400 by 2050, a change of 7% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network, including two in Dyffryn Ardudwy - land adjacent to Pentre Uchaf and land adjacent to Capel Horeb

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Arto catchment the biggest risks indicated by the RBCS are equal across five indicators - catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography), other RMAs, WINEP, sewer collapses and external sewer flooding.

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, pollution, internal and external flooding, and frequent flooding due to storms are the biggest risks in the Arto catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, pollution, internal and external flooding, and frequent flooding due to storms are the biggest risks in the Arto catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to be in the Extended or Complex category and required a more detailed option assessment.

Figure 6 - Associated Strategic Planning Area priority (2025)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Moderate	Poor	Bad
Artro	6	2	4	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Кеу	
	Headroom							Pass	Close fail
								Close Pass	Fail
Artro	Wet weather capacity							>90%	70%-80%
								80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Artro catchment the balance between supply and demand currently passes the assessment criteria available, for headroom only, and will continue to pass through to 2050. There are currently no local issues present in the L4 catchments.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience					
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term			
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term			
50% Reduction reduction in area draining to the combined sewers	Represents removal of runoff from any connected area including residential properties. There are likely to be multiple stakeholders to engage with.	Long term			
	Improving Headroom				
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term			
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term			
Reducing trade flow	Reduce trade flows by around 25% by application of water efficiency measures.	Long term			

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)	
Maintain existing performance*	-	£8,000,000.00	£8,000,000.00	
40 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00	
20 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00	
10 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00	
0 spills in a typical year	£5,000,000.00	£9,000,000.00	£9,000,000.00	
Equivalent No. Principality Stadiums full of water in 10 spills	53.00	53.00	54.00	

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)	
Internal escapes	£0.00	£0.00	£0.00	
External escapes in gardens	£700,000.00	£800,000.00	£1,200,000.00	
Escapes in highways	£3,700,000.00	£4,600,000.00	£4,900,000.00	
All other remaining flooding	-	£0.00	£0.00	
Total	£4,400,000.00	£5,400,000.00	£6,100,000.00	

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

Table A1 - Number of schemes in L4 catchment within L3 catchment

L4 Catchments	No. Schemes
LLANBEDR (GWYNEDD)	0
DYFFRYN ARDUDWY STW	0

Appendix B - Risk Based Catchment Screening

Table B1 -	Risk Based	Catchment Screenin	ng (RBCS) indicators

Indicator	Description
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme wet weather event.
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).
Discharge to sensitive waters (part A)	Mechanism to understand the significance of
Discharge to sensitive receiving (part B) (Tier 2)	environmental receptors.
SOAF	Considers current / potentially future activity instigated by SOAF procedures.
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.
M/WT/M/ O compliance	Historical measure relating to the performance

wwwwwwwqcompliance	compliance (numeric)).
WwTW DWF compliance	Historical measure of compliance with flow permits.
Storm overflows	Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).
Other RMA systems	A mechanism to understand risk posed by other RMA assets in the catchment.
Planned residential development	Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.
WINEP	WINEP sets out the actions that companies will need to complete to meet their environmental obligations.
Sewer Collapses	Historical measure that identifies risks to the integrity of the sewer system.
Sewer Blockages	Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.
Bespoke Indicators (Tier 2)	Not applied in cycle 1.

DWMP Strategic Planning Area Summary

Dulas North

1.0 Introduction

This Drainage and Wastewater Management Plan (DWMP) sets out how we as Dŵr Cymru Welsh Water (DCWW), will manage and improve our assets to maintain a resilient and robust wastewater drainage system. The plan aims to manage flooding and pollution from our wastewater assets in the future, for our customers and our environment by working collaboratively with stakeholders, regulators and local authorities to provide a complete partnership in tackling current and future problems.

1.1 Catchment Information

The Dulas North planning catchment lies within the Meirionnydd catchment (see Figure 1).

The Dulas North catchment is in West Wales. The River Dulas flows down into the River Dyfi. Corris and Esgairgeiliog Ceinws are the largest urban areas.

This planning catchment consists of 6 wastewater catchments (see Figure 2). There is a combined population of 1158, this is set to decrease to 900 by 2050, a change of -24%. There is a total sewer length of 8km, with a foul sewer length of 1km, a surface water length of 0.65km and a combined sewer length of 7km. There are 6 Wastewater Treatment Works (WwTW), 2 Sewerage Pumping Stations (SPSs), and 3 Combined Storm Overflows (CSOs) across this strategic planning area.

Figure 2 - Tactical planning catchment (dark green) and WwTW catchments (blue)

2.0 Stakeholder Engagement

The DWMP aims to enable DCWW to work collaboratively with stakeholders, regulators and local authorities to tackle current and future challenges. DCWW has identified stakeholder objectives that align with the aims of the DWMP and goals of other management plans.

Further information on how we are and will continue to engage with stakeholders can be found in the 'How have we engaged with customers and stakeholders?' chapter of the Main Plan.

Stakeholder Engagement Opportunities

Stakeholder engagement meetings commenced in 2022. These meetings are being held between DCWW and the respective parties, such as NRW, EA, Councils and ENGO's. Further information of the outcome and points of focus towards short and long term strategy planning will be provided in the next cycle of the DWMP assessment.

Table 1 - Stakeholder opportunity partnerships

The 'Where we want to work with you' document, which further explains our stakeholder engagement plan, can be found in the Risk section of the DCWW DWMP page found here: Drainage Wastewater Management Plan

3.0 Risk

We have assessed our likely performance from now to 2050 against the objectives that we set in our most recent business plan. The results of this assessment are presented in the following sections.

To understand future performance, we need to estimate how much population will change by, the degree to which climate change will impact Wales and areas of England which are within our operating region, and how further surface water connected to the sewer network might increase the amount and rate at which rainfall drains into our sewers.

Urban creep is the term used to explain loss of green spaces. For example, when new driveways or house extensions are built. This often leads to more rainwater entering sewers. Our forecasts, which are based on a UKWIR study, suggest that urban creep will add up to 0.63 metres squared of impermeable area per house per year.

A UKWIR report on urban creep can be foundhere, Impact of Urban Creep on Sewerage Systems.Climate change is predicted to increase the intensity of storms by around 35% in this region. This is based on a

2017 UKWIR report, which used a high-resolution climate model for the UK to predict changes in design storm intensities for a high emissions scenario (RCP8.5). In a typical year, winters are likely to be warmer and wetter, and summers generally drier. More intense rainfall will happen more frequently. The population in the Dulas North region is set to decrease to 900 by 2050, a change of -24% based on our future projections. For a further a breakdown of population change in the L3 region please see the L4 report.

There are major developments in localised areas that will contribute to future pressures on the network

The core management plan for the Meirionnydd provides an overview of the conservation required on site. The plan details the drive in enhancing the social, economic and natural value of the area, by summarising conservation objectives with regards to maintenance, restoration and future connections between the wider ecology and connecting surroundings. The plan can be found here:

Core Management Plan

Future predictions of growth in the area have been estimated based on the average between the rate of properties that have been built in the past 10 years and the rate that the local development plan predicts houses should be built. In addition to this, we have accounted for the changes in the existing population by the change in the number of people living in an average property in the area.

3.1 Risk Based Catchment Screening

The Risk Based Catchment Screening (RBCS) is the initial screening process to determine if a more detailed risk assessment is required. The assessment screens catchments against planning indicators which have been stipulated in the national guidance for DWMPs. The results are shown in Figure 3. Descriptions of the indicators can be seen in Appendix B. All catchments passed through to a more detailed risk assessment (BRAVA).

For the Dulas North catchment the biggest risks indicated by the RBCS are - catchment characterisation (based on a vulnerability assessment of flooding due to local characteristics e.g. topography).

RBCS Results

*To sewer flooding due to extreme wet weather events.

**Categorised as a "planned" scheduled action within the Natural Resources Wales Action Database or considered as "Remedy" on Natural England Designated Sites system.

***Categorised as a "identified" scheduled action within the Natural Resources Wales Action Database or considered as "Threat" on Natural England Designated Sites system.

+Frequency investigation triggered.

++Overflow risks not covered by other indicators,

Figure 3 - Risk Based Catchment Screening results

3.2 Baseline Risk And Vulnerability Assessment (BRAVA)

Following on from the RBCS, the Baseline Risk and Vulnerability Assessment (BRAVA) highlights current and future risk. The risk scores are driven by company targets which were set in our last business plan. These targets were subdivided according to population or sewer length, depending on the measure, to derive a target for each river basin catchment. Figures 4 and 5 illustrate the outcome of the BRAVA assessment for this strategic planning area.

Figure 4 - BRAVA 2025 Summary

In 2025, sewer collapses are the biggest concern in the Dulas North catchment.

Figure 5 - BRAVA 2050 Summary

In 2050, sewer collapses are the biggest concern in the Dulas North catchment.

Figure 6 and 7 indicate the 2025 and 2050 risk of both flooding and pollution caused by a lack of hydraulic capacity across our operating region. These maps illustrate where the issues occur and where we want to work with local communities and stakeholders to resolve issues. By working together, we can combine knowledge and resources to deliver the best outcomes for local communities and the environment.

From the completion of the BRAVA analysis, we assessed the problem characterisation of the risks identified. This catchment was concluded to require a standard option assessment methodology.

Figure 6 - Associated Strategic Planning Area priority (2025)

Figure 7 - Associated Strategic Planning Area priority (2050)

3.3 Water Framework Directive

Since 2000, the Water Framework Directive (WFD) has been the main law for water protection in Europe. It applies to inland, transitional and coastal surface waters as well as groundwaters. It ensures an integrated approach to water management, respecting the integrity of whole ecosystems, including the regulation of individual pollutants and setting corresponding regulatory standards. It is based on a river basin district approach to make sure that neighbouring countries manage the rivers and other bodies of water they share.

Table 2 shows a count of river waterbodies managed under the WFD in this region and WFD status' they have achieved in Cycle 2 (2015).

L3 Area	Total	Good	Moderate	Poor	Bad
Dulas North	2	0	2	0	0

Table 2 - WFD status'

4.0 Supply Demand

Supply-demand is an assessment of the capacity of our treatment works. It approximately assesses whether all the treatment works in a region can collectively cope with current and future flows in dry and wet weather. There are two parts to the assessment: dry weather flow (DWF) and a wet weather capacity assessment.

For the DWF part of the assessment, the suitability of the DWF consents is tested against forecast future growth and changes in water consumption. In the north of our operational area, population is expected to decrease by 2050, and in the south, it's expected to increase. We're aiming to reduce water consumption to 100 litres per person per day by 2050 so this has been accounted for in the assessment. The shade of blue indicates how much "headroom" the treatment works is thought to have at each time horizon – with the lighter shades of blue indicating more spare capacity at our treatment works, i.e. more "headroom". If an area cannot cope with the expected DWF, then without investment, we would expect final effluent quality to decrease.

The wet weather assessment takes pass forward flow (PFF) consent values, where available, as an indication of WwTW capacity, and estimates the amount of incoming flow the treatment works is able to treat across a year. It uses the same estimates as the DWF assessment for current flow, but also includes an estimate as to how much rainfall the WwTW might be able to deal with in the future, by including growth, climate change and creep. Climate change is expected to change the periodicity and amount of rain across a "typical" year. Creep, the gradual misconnection of storm sewers to the foul sewer network, is also expected to have an impact on the amount of flow a WwTW receives during storms. This gives us an approximation of where we might expect problems to arise in the future during wet weather due to growth, creep, and climate change. Areas with the greatest estimated wet weather treatment shortfall are shown in the darkest blue.

L3 Area	Assessment	2025	2030	2035	2040	2045	2050	Ke	еу
	Headroom							Pass	Close fail
								Close Pass	Fail
Dulas North	Wet weather capacity							>90%	70%-80%
	. ,							80%-90%	<70%

Table 3 - Supply Demand Balance

Table 3 shows that for the Dulas North catchment the balance between supply and demand currently passes the assessment criteria available, for headroom only, and will continue to pass through to 2050. It should be noted that local issues are present in the Esgaireiliog (Ceinws) L4 catchment. Further detail is provided in the relevant L4 summary.

5.0 Options

To analyse a catchments response to rainfall we use design storms. A design storm is the use of artificial rainfall where the total rainfall depth has a specified return period. Design storms represent the statistical characteristics of rainfall derived from analysis of many years of actual rainfall records. They are easier to use than observed rainfall and can approximate a catchment's rainfall in just a few storms. In sewer modelling, these storms may be used for peak flow, surcharge and flooding analysis and for the development of flooding solutions and peak screening rates for CSOs. The notation we use for design storm is a 1 in X year event, for example a 1 in 1 year event is rainfall which we might expect to occur on average once a year, or a 1 in 30 year event is a rainfall event which we might expect to occur, on average once every 30 years.

Over time the pressures on our sewerage network change due to influences such as catchment growth, creep of rainwater into the network, or influences such as climate change impacting rainfall patterns. To ensure the plan is robust over the 30-year planning horizon we have tested various types of schemes, and combinations of schemes, to ensure a robust plan is delivered. Table 4 shows different ways that we can reduce the risks to customers and the environment. We can stop rainwater entering our sewers from homes (domestic surface water disconnection), businesses or paved areas (commercial and paved surface water disconnection) or from roads (highway area disconnection). Sometimes water gets into sewers through small gaps that can occur in ageing sewers - by replacing or repairing the sewers we can reduce the likelihood of this happening (groundwater infiltration into sewers reduction). Reducing how much water homes and businesses use can also help to reduce the risk to people and the environment (personal water usage reduction or trade flow reduction).

Improving Resilience					
10% Reduction in area draining to the combined sewers	Represents removal of runoff from large commercial buildings.	Short term			
25% Reduction reduction in area draining to the combined sewers	Represents removal of area runoff from non-residential paved areas where there is only one stakeholder (e.g. Local Authority or Highways Agency).	Medium term			
50% Reduction reduction in area draining to the combined sewers	0% Reduction reduction in area draining to the combined sewers stakeholders to engage with.				
Improving Headroom					
Reducing infiltration	Reducing infiltration into sewers by 50%, which could be achieved by relining or replacing the public sewers.	Medium term			
Reducing water use	Represents a reduction in water use per person to around 100l per person per day by 2050 by application of water efficiency measures.	Medium term			
Reducing trade flow Reduce trade flows by around 25% by application of water efficiency measures.		Long term			

We have undertaken an analysis of all our wastewater catchments to determine the benefit in terms of potential volume of water removed from our systems for each scheme type to determine a Journey Plan, see Figure 8. The Journey Plan provides an indicative overview of the most effective option types against a timeline indicating when they might be applied.

Journey Plan

Figure 8 - Journey Plan

The measures within the Journey Plan include all green infrastructure and surface water removal techniques. We have undertaken analysis to determine the likely costs to mitigate future predicted pollution and flooding. Mitigating the risk posed by flooding has been assessed in terms of the probability of occurrence. We use the size of a storm event that has the probability of occurring once every 30 years.

Table 5 highlights the potential costs required to ensure CSOs maintain their existing performance and spill no more than a maximum of that indicated in the scenario within a 'typical year'. To achieve this we need to offset any future impact on our assets, ensuring we continue to maintain the level of service provided. The cost assessment calculates the impact of rainfall and drainage contributions to the network relative to today's costs and we assess CSOs based on the number of times they are predicted to spill in a 'typical year'.

Table 6 highlights the potential costs in this region from preventing flooding from manholes scenarios. The assessment includes both the size and cost of potential mitigation measures.

Costs in Table 5 are in addition to those in Table 6, for example, in order to achieve 10 spills in a typical year across all our assets in this region, no internal escapes and no external escapes in gardens, these three costs need to be added together.

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)	
Maintain existing performance*	-	£7,000,000.00	£10,000,000.00	
40 spills in a typical year	£1,000,000.00	£1,000,000.00	£1,000,000.00	
20 spills in a typical year	£2,000,000.00	£2,000,000.00	£2,000,000.00	
10 spills in a typical year	£4,000,000.00	£4,000,000.00	£4,000,000.00	
0 spills in a typical year	£7,000,000.00	£7,000,000.00	£8,000,000.00	
Equivalent No. Principality Stadiums full of water in 10 spills	10.00	12.00	13.00	

* Maintain is a considered scenario where we will continue to maintain the current level of service within the region and improve the network and address known and emerging risk.

Table 5 - Summary of Combined Sewer Overflow Option Investment Strategy Costs

Choice of Scenario	Current Scenario (£)	2030 Scenario (£)	2050 Scenario (£)
Internal escapes	£0.00	£0.00	£0.00
External escapes in gardens	£0.00	£0.00	£0.00
Escapes in highways	£0.00	£0.00	£0.00
All other remaining flooding	-	£0.00	£0.00
Total	£0.00	£0.00	£0.00

*Internal escapes - All flooding that results in flooding within a property is stopped

*External escapes in gardens - All flooding within the curtilage of the property is stopped

*Escapes to highways - All flooding from DCWW systems impacting public highways is stopped.

Table 6 - Summary of Flooding Option Investments Strategy Costs

We have developed solutions which aim to provide a resilient sewerage network when tested against a range of future legislative scenarios. The solutions developed highlight the level of investment required to bring the entire network up to the level of protection required to be resilient to future demands. We have derived costs for a range of potential legislative future scenarios to ensure the cost impact of choices made is recognised.

We are beginning to break down the investment indicated in Table 5 and 6 by creating practical schemes ready for delivery. These schemes are designed as traditional engineering solutions, sustainable or green infrastructure, or a combination of both. These packages have then been analysed in terms of their long term benefit and environmental and social cost to society and one has been chosen for inclusion as our preferred best value option. The areas where we have started our delivery programme aims to provide protection, to our worst served customers and rivers designated as Special Areas of Conservation (SAC) under the Habitat Directive, as a priority against drainage and network failure which result in pollution events and flooding. The solutions developed highlight the level of investment required to bring our network to the level of protection required to mitigate against these risks. Appendix A shows the number of solutions within this tactical planning unit (Level 3).

For more information on the methodology developed to carry out the assessments see the DWMP Main Plan.

If you would like to work with us to develop joint projects to reduce the risk of flooding and protect the environment, please contact us at DWMP@dwrcymru.com.

We will continue to work with the Welsh Government, Regulators and Local Authorities about the pace, scale and affordability of improvements to be made.

We will be consulting on the preferred approach to planning and once its concluded the next stage is to develop the pipeline of options to meet the pace scale and affordability discussed with Welsh Government and our regulators.

Appendix A - Schemes in L4 catchment within L3 catchment

The information provided in this summary is the culmination of the DWMP framework methodology and does not currently include other industry methodologies such as National Environment Programme, Water Industry National Environment Programme or Price Review 2024. Further work to integrate these methodologies will continue after this publication.

L4 Catchments	No. Schemes

Appendix B - Risk Based Catchment Screening

Table B1 -	Risk Based	Catchment Screenin	g (RBCS) indicators

Indicator	Description
Catchment Characterisation (Tier 2)	Provides a mechanism to understand the vulnerability of the catchment/subcatchments to sewer flooding as a result of an extreme wet weather event.
Bathing or shellfish waters	Mechanism to understand the significance of any impact of water company operations on environmental receptors (bathing or shellfish waters).
Discharge to sensitive waters (part A)	Mechanism to understand the significance of
Discharge to sensitive receiving (part B) (Tier 2)	environmental receptors.
SOAF	Considers current / potentially future activity instigated by SOAF procedures.
CAF	Provides an indication of capacity constraints in the network as a leading indicator to service failure.
Internal Sewer Flooding	Historical measure that records the number of internal flooding incidents per year (sewerage companies only).
External Sewer Flooding	Historical measure that records the number of external flooding incidents per year (sewerage companies only).
Pollution Incidents	Historical measure that identifies incidents of unexpected release of contaminants that have resulted in environmental damage.
M/WT/M/ O compliance	Historical measure relating to the performance
compliance (numeric)).	

Historical measure of compliance with flow permits.	
Examines issues associated with all storm overflows not captured by other indicators (e.g. issues to be considered include non- compliance with pass forward flow conditions, storm storage conditions (where relevant) and screening requirements).	
A mechanism to understand risk posed by other RMA assets in the catchment.	
Uses predicted residential population growth forecasts to target catchments requiring investigations for potential future capacity constraints.	
WINEP sets out the actions that companies will need to complete to meet their environmental obligations.	
Historical measure that identifies risks to the integrity of the sewer system.	
Historical measure that records obstructions in a sewer (that require clearing) which causes a reportable problem (not caused by hydraulic overload), such as flooding or discharge to a watercourse, unusable sanitation, surcharged sewers or odour.	
Not applied in cycle 1.
